Reflection #2

Upon changing the x value, it produced a very noticeable effect on each line of the poem. In my case I used x value 45 which made it so that the model was choosing words with a way less likely probability compared to the words closer to the top of the list. By choosing this x value it made the poem's reasoning way more unpredictable as the words chosen were way less likely. For example, "distant glitter" became "distant horizon", and "nothing himself, behold" became "nothing himself, behaved. There were also lines from the poem that became humoristic after having its last word changed. The most absurdest line was "...have been cold a long time" that became "...have been cold a long fucking".

I could tell very clearly that the higher the x value became, the more nonsensical the poem became, as the words getting used kept becoming less and less likely. Although some of the words still worked and kept correct grammar, it always left other sentences sounding unusual or changing the sentence's complete meaning. As a final thought I came to decide that by increasing the x value you move the understanding of each line further away from the model's most likely word, creating a more unexpected result.

In a P+7 technique in which all nouns are replaced with their 7th highest probability alternatives, I would first use an ai model to help me identify all nouns and then find each one's 7th highest probability alternatives. In my code I would then have it set up to replace all the identified words with their 7th highest probability.
